## 1. Welcome to TrueLift

---

TrueLift is a strength-training app designed so anyone can follow a serious routine, log their sets and make sound progress without needing to understand sports programming. You train and record what you do; the app tells you when and by how much to increase the weight, when to hold back, and how your progress is developing over time.

The central idea is simple: strength progress is not about adding weight recklessly, but about applying small, sustainable increases at the right time. TrueLift analyses your records - weight, repetitions, RIR, effort and daily readiness - and turns them into a clear recommendation for your next session. The more accurately you log your training, the better it can coach you. Section 8 explains which data the engine uses and why it matters.

This manual takes you through the app from start to finish: initial setup, every tab, all tools, optional features and the most common questions. You do not need to read it all in one sitting; use it as a reference whenever you have questions about a screen.

*Important: TrueLift It is a support tool for your training, not a substitute for medical judgment. If you have discomfort or health questions, consult a professional.*

## 2. Free version and PRO version

---

TrueLift is **free** In its essential part: you can configure your routine, record your sessions, receive automatic weight gains and track your progress without paying anything. Some advanced features are part of the **PRO version**, which you can unlock with the payment method you prefer: subscription, annual payment or lifetime payment.

### What each version includes

| Function                                                                | Free | PRO |
|-------------------------------------------------------------------------|------|-----|
| Record sessions and automatic progression                               | Yes  | Yes |
| Cardio, disc calculator and warm-up                                     | Yes  | Yes |
| Rest timer with alarm                                                   | Yes  | Yes |
| Weekly volume and frequency                                             | Yes  | Yes |
| Progress, personal brands and performance                               | Yes  | Yes |
| Share training and monthly report                                       | Yes  | Yes |
| Backups                                                                 | Yes  | Yes |
| Change one exercise for another                                         | Yes  | Yes |
| Manual deload mode (deload)                                             | No   | Yes |
| Adjust sets, RIR, reps and rest                                         | No   | Yes |
| Personalize your routine in terms of movement patterns, sets, laugh etc | No   | Yes |
| Rename routine sessions                                                 | No   | Yes |
| Create new exercises in the library                                     | No   | Yes |
| Import a routine from Excel template                                    | No   | Yes |
| Self-regulation (daily status)                                          | No   | Yes |
| HRV (heart rate variability)                                            | No   | Yes |
| Diet phase (deficit/surplus)                                            | No   | Yes |
| Suggested automatic download                                            | No   | Yes |
| Indicator Status for training (0–100)                                   | No   | Yes |
| Pain per area (stops only the affected exercises)                       | No   | Yes |
| Cardio load integrated into fatigue signals                             | No   | Yes |

In the free version, the **diet phase** is fixed in Maintenance, and self-regulation and HRV are disabled. Everything else works normally.

Is PRO worth it? The free version gives you a complete progression engine that makes decisions based on what you do in the gym. PRO also sees what happens outside it: sleep, stress, pain and its location, HRV, diet phase and cardio load. With these signals, the engine decides not only how much to increase the weight, but also when to push, when to hold back and when to protect you with a deload. If you take training seriously, that difference compounds over months of progress. You can try it free for 28 days.

### Free 28-day PRO trial

You can try **all PRO features for 28 days, free**, without entering any payment information. When you try to use a PRO feature (or from the Author tab), you will see the PRO version screen with the button **Try 28 days free**. Pressing it immediately activates all advanced functions.

- During the trial, the Author tab shows how many days you have left. Each time you open the app, a reminder appears with the buttons OK and Buy PRO version.
- The home cover changes to the PRO version while the trial is active.
- When the 28 days end, PRO features are locked again and the app returns to free mode. Your routine and history are not lost; those advanced options simply become unavailable until you purchase the full version.

*The test is for single use per user.*

### Buy the PRO version

To get PRO features, press **Buy PRO** on the PRO version screen. All payments are managed through Google Play, with the usual methods of your account (card, Google pay, operator balance, etc.). You can choose between three modalities: **subscription** (recurring payment that you can cancel whenever you want), **annual payment** (one full year of PRO) and **lifetime payment** (a single payment that does not expire). The price of each modality is shown on the purchase screen itself. Once activated, your purchase is associated with your Google account: if you change your phone or reinstall, press **Restore purchase** and it will be reactivated without paying again.

## 3. Getting started: set up your routine

---

The first time you open TrueLift you get to the screen **Set up your routine**. Here you define the starting point. You can return to it at any time with the settings icon (top right).

### For whom?

Choose **Man** either **Women**. This selects the most suitable base routine template as a starting point (you can customize it later).

### Progression system

Decide how you want to progress:

- Simple linear progression: fixed repetitions. When you complete every set at the target number of reps and planned RIR, the app increases the weight for the next session. It is ideal if you have been training for less than two years, because it allows frequent increases.

- **Double progression:** you work with a **range** of repetitions (e.g. 8–12). You build up reps with the same weight until you complete all sets at the high end of the range; then the app tells you the new weight. It is ideal when linear progression has stalled.

### Training days per week

Choose between **2 and 5 days**. The structure of the routine (what is trained each day) automatically adjusts to the chosen number of days.

### Your body weight

Select your body weight with the wheel. It is used for bodyweight and weighted exercises (pull-ups, dips and push-ups), where the load you move includes your own body, so strength estimates remain realistic. Keep it up to date: the engine uses it both to suggest loads and to measure your actual progress in these exercises, including assisted variations.

When you finish, press **Continue with this routine** to enter the app.

## 4. Set up your material

---

So that the weight gains that it proposes to you TrueLift be **really chargeable** With your equipment, take a moment to indicate what plates and dumbbells you have. You will find all this on the settings screen.

### 1.25 kg discs

Activate it if you have pairs of 1.25 kg disks (assumed unlimited). Allows **finer load jumps** on the bar: instead of going up from 2.5 to 2.5 kg per side, you can slim down to 1.25 kg per side.

### Fractional disks (microcharging)

They are the discs **smaller** what do you have for microcharges (by example of 0.5, 0.75 or 1 kg). It indicates two things:

- **Smallest disc weight-** The value of the fractional disk you own.
- How many per side: choose 1 to 4, or Unlimited. This matters because if you only own one pair of 0.5 kg plates, the app will not suggest an increase that requires three plates per side.

Standard discs (2.5 / 5 / 10 / 20 kg, and 1.25 kg if you activate them) are considered unlimited.

### Jump between dumbbells

Indicate the difference in weight between one dumbbell and the next one in your gym (for example 2 kg). It is used to calculate the target weight for dumbbell exercises, so that it proposes a weight that **exist** in your rack.

### Countdown between sets

If you activate it, writing down the repetitions of a sets automatically starts the **rest timer** until the next one. You can deactivate it if you prefer to control the breaks yourself.

## 5. The five tabs

---

The bottom bar has five tabs. This is the overview; each is detailed below.

- **Routine:** your training plan. Here you see the days, exercises, sets, reps, RIR and rest, and you can customize it.

- **Volume:** how many effective sets you do per muscle group per week and how often, with a color reference.
- **Log:** the heart of the app. This is where you record each workout and your cardio. When you open the app, it selects this tab and preselects your next session.
- **Progress:** graphics and brands. Tonnage, estimated 1RM, evolution per session, personal bests, performance and the monthly report.
- **Author-** information about the author, links and activation of the PRO version.

At the top right, at any time, you have quick access to the **disk calculator** (dumbbell icon) and **change your selection** (settings icon).

## 6. Routine Tab

---

The Routine tab shows your plan organized by **days/sessions** (upper lashes). Each exercise appears on a card with its movement pattern, muscle group and parameters.

### Actions in each exercise

- **Change exercise** (free): replaces the exercise with another option from the same pattern and group. Useful if your gym doesn't have a specific machine.
- **Change pattern** (PRO): Change the movement pattern of the gap (for example, from horizontal thrust to vertical thrust).
- **Sets, RIR, Reps and Rest** (PRO): Adjust each parameter with the + / – buttons. In the free version these controls show the PRO screen.
- **Remove exercise** (trash): Delete that day's exercise.

Underneath each day you have **Add exercise** (adds a new line to that session) and **Restore original routine** (undo all your changes and return to the default routine).

### Rename sessions (PRO)

Each session has a button **Rename session**. With PRO you can change the name of the day (for example, call it "Push" or "Leg A"), something practical if you build your routine from your mobile. When renaming, the history of that session is preserved so you don't lose your progression.

### Library and templates

- **New exercise in the library** (PRO): Create your own exercise (with your name, pattern and group) to use in your routines.
- **Download template** (free): you get an Excel template to design your routine comfortably from your computer.
- **Export your routine to Excel** (PRO): Download your current routine already uploaded to the Excel template. So you can use it as a base, reorganize exercises, sets, repetitions, RIR and rests comfortably from your computer and, when you're done, import it again.
- **Import** (PRO): upload the completed Excel template and the app rebuilds your routine from it. This completes the cycle: export your routine, edit it comfortably in Excel, then import it again so TrueLift applies it exactly as configured.

## PRO routines ready to train (PRO)

If you have PRO, you don't need to design your routine from scratch: the app can automatically download a collection of PRO routines already designed and ready to train. They are complete and direct plans, designed to cover practically any situation: for men and women, for different numbers of training days per week, for those who have a lot of equipment or very little, and for those who have more time per session or need to train in less time. The idea is that you find an option that fits your context without prior work: you choose the one that best suits you, load it and start recording. From there it progresses like any other routine, and you can continue adjusting it or export it to Excel if you want to fine-tune it.

## Top set + back-offs (PRO)

What it means. The top set is your heaviest set of the day: the first set of the exercise, performed with the highest weight and lowest RIR. It establishes your level and drives progression. The back-off sets come afterwards at a slightly lower weight - using your chosen back-off percentage - to accumulate quality volume without repeating the maximum load. The aim is to push one genuinely demanding set, reduce the load slightly, and continue adding effective work with good technique. In practice, you give your best effort on the top set and complete the back-offs with more reps in reserve.

In the routine editor, main exercises (the "large" movement pattern) display a Top set + back-offs switch. When enabled, two settings appear: back-off percentage (5-30%, in 5% steps) and back-off RIR (0-4). Set 1 is the top set; every remaining set is a back-off.

In the Log tab, the weight field changes to "kg (top)". Each back-off has its own kg field, automatically filled as top-set weight x (1 - %) and rounded to a load you can assemble with your plates. If you change the top-set weight, the back-offs update with it; if you edit a back-off manually, that value is retained. The target RIR for back-offs is filled separately and also reflects deload or daily-readiness adjustments.

Progression and metrics: only the top set determines exercise progression, including the repetition target, e1RM, plateaus and personal records. Back-off sets contribute to session performance, intra-session fatigue, automatic unloading and tonnage. They are not intended to progress independently: their weight is based on the selected back-off percentage, and you only need to complete reps up to the target RIR. Even so, every set - top and back-off - is included in volume calculations.

Excel: the template adds three columns to each training day: H, Top+Back (yes/no), with a dropdown; I, back-off % (5-30); and J, back-off RIR (0-4), plus a note in Instructions. When imported, TrueLift reads these fields. Blank cells or "no" are treated as straight sets, so existing templates remain unchanged.

## 7. Your daily life: register a session

---

You will spend most of your time in the Log tab. When you open the app, it is already positioned on the next session due - the one after the last session you saved.

### Before starting

- Above you see the **selected session** and the **week** of that session. Each session type progresses independently.

- For each exercise, the app shows the Target (sets x reps - RIR) and, below it, Last time (the weight and reps completed previously), giving you an immediate reference.
- The suggested weight is filled in automatically and is always a load you can assemble using the equipment configured in the app.

### Record the session

For each set, enter the repetitions you completed and the RIR (repetitions in reserve: how many more reps you could have performed before failure). Enter the weight used; you may leave it at 0 for exercises with no external load. A progress bar shows the percentage of the planned work completed, together with a reference margin.

What is RIR? It is a simple way to measure effort: RIR 2 means you could have completed two more repetitions before failure. Recording it accurately is essential for precise progression. Be honest: overstating RIR produces unrealistic increases that you may not complete later. If you omit it on a given day, the app protects you by applying only a small, cautious increase until that signal is available again, and it will remind you in the recommendation message.

Record the actual RIR for every set. Do not enter one value from memory for the whole table: record each set separately, exactly as it felt. The app evaluates sets individually, not as a rough average, and every RIR affects how it interprets your effort, estimates your strength and selects the next increase. With straight sets, the goal is to reach the target reps on every set - or the top of the range on every set in double progression - while recording the true RIR for each. This lets the engine manage progression accurately; two sessions with the same reps but different RIR values lead to different decisions. One important detail: do not exceed the planned reps simply to force a lower RIR. If the target is 3 x 8-10 at RIR 1 and you reach 10 reps on the first set with two reps still available, record 10 reps and RIR 2; do not perform an eleventh rep just to report RIR 1. The higher-than-planned RIR is exactly the signal the engine needs. The rule is simple: you progress when every set meets the repetition target and the overall RIR is at least the target. That confirms you control the weight and are ready to increase it. If overall RIR is below target, the engine understands that the load still needs to be consolidated even if you completed the reps.

### Save and messages

By pressing **Save session**, TrueLift analyzes what you have done and responds with a clear message:

Before saving you can rate the **session effort (RPE, 1 to 10)**. It's optional and only counts if you touch it, but it's worth it: the engine uses it to fine-tune the next climb and monitor your accumulated fatigue (more detail in section 8).

- A message from **performance** that assesses how the session went compared to what was expected.
- A notice of **new record** if you have improved your best estimated 1RM in a main (multi-joint) exercise.
- Congratulations for **streak** if you chain complete weeks of training.
- Context-aware messages: if you save a session on an amber or red day, the app reminds you that slightly lower performance is expected. During a deload week, it confirms that performance is not being evaluated; this is intentional, not an error.

If you have the stopwatch activated between sets, writing down each set starts the **rest countdown**.

### Rest timer and alarm

The stopwatch counts the rest between sets and **an alarm sounds** when finished, even if you have the screen off or are listening to music (the alarm is mixed with the audio, it does not cut it). The screen stays on while the count is running so you can see the remaining time.

### Record cardio

Use the Record cardio button to log cardio sessions. Choose a type, or enter your own name, then add duration in minutes and intensity or effort (RPE from 1 to 10). Cardio appears in your history and calendar.

Cardio is more than a note. From duration and effort, the engine calculates weekly cardio load and compares it with your normal level. A clearly harder-than-usual week becomes a fatigue signal and, with autoregulation (PRO), may contribute to a deload suggestion. Record cardio accurately, especially when combining strength and endurance training.

### History

Below the logging area is your session history, loaded efficiently even when it contains hundreds of entries. Sessions logged in real time also include their duration. From each session you can:

- Share: generate an attractive workout image ready for social media.
- Edit: correct the weight, repetitions, RIR or date of a saved session.
- Delete: remove that session.

You can also **Export to Excel** the entire history, or **Delete all history** (with double confirmation, for security).

## 8. Your data is the engine: what to record and why

---

TrueLift does not guess: it learns from you. Every recommendation in the app - the suggested weight, the message shown when you save, or a deload suggestion - comes from an engine that analyses your records and turns them into decisions. The consequence is direct: the quality of the app's recommendations depends on the quality of your data. This section explains which signals the engine uses and what each one contributes to your training.

*We don't go into the formulas (that logic is private), but we do go into what interests you: what data the engine uses, what it uses it for and why it is worth recording it well.*

### Weight and repetitions: the basis of everything

Each set you record feeds into the estimate of your actual strength (the estimated 1RM). The engine is not limited to your best sets: **combines the best with the set of the session**, so that a specifically optimistic sets does not inflate the recommendation. With that estimate you decide if it is time to raise, how much to raise and when it is convenient to consolidate.

In bodyweight or weighted exercises (pull-ups, dips, push-ups), the motor calculates your strength with **your body weight plus ballast** —also in assisted exercises—. That's why it's important to keep your body weight updated in your settings: if it changes and you don't update it, your estimates and progress graph drift without you noticing.

## The RIR: the small piece of information that changes things the most

RIR (repetitions in reserve) tells the engine how close to failure you are training. It lets the app fine-tune each increase: if you have plenty of reps in reserve, it can be slightly more ambitious; if you are at your limit, it protects you. Two tips:

- **be honest.** An inflated RIR translates into unrealistic force estimates and weights that don't work out later. It is better to fall short than to exaggerate.
- Do not leave it blank. If you omit RIR one day, the app still works but becomes cautious: it applies only a minimal increase until that signal returns. Recording less data never produces more aggressive recommendations; by design, it produces more conservative ones.

## Session effort (RPE)

When saving a session, you can rate its overall effort from 1 to 10 (RPE). This is optional and only counts if you select a value; the app never invents one for you. If recorded, the engine uses it to adjust the next increase - meeting the target comfortably is not the same as barely completing it - and to monitor accumulated internal load, one of the signals that can reveal fatigue before it appears in your weights.

## Cardio counts too

Cardio is no longer a simple entry on the calendar. Using the duration and effort (1–10) you record, the engine calculates your **weekly cardio load** and compares it with what is usual for you. A week of cardio that is clearly more demanding than normal counts as a sign of fatigue and, with self-regulation (PRO), can motivate the suggestion of a deload. If you combine strength and endurance, record all your cardio with realistic data: it's the only way for the app to see your entire workout, and not just half.

## Record in the moment, not from memory

Record each set as you perform it. RIR recalled hours later is far less reliable. When you log in real time, the app also records session duration automatically, which you can see in your history. Consistent records made using the same criteria are more valuable than occasional perfect records: the engine learns from patterns, and patterns require consistency.

## How fatigue is calculated

The app does not measure fatigue with a sensor; it infers it from the signals you record and always compares them with what is normal for you, not with an absolute value. Four factors carry the most weight: the actual RIR of your sets, performance relative to your baseline, the session RPE entered when saving, and your weekly cardio load. With PRO autoregulation, daily readiness - sleep, stress, discomfort and energy - and HRV are also included. The engine does not react to one isolated bad day. It watches trends across several sessions, so a temporary dip does not slow you down, while sustained fatigue reduces the rate of progression and, when pronounced, triggers a deload suggestion. Back-off sets and tonnage also contribute to this internal-load assessment. The more complete and honest your records are, the better the app can distinguish between being ready to push and needing to recover.

## With PRO, the engine sees twice as much

Everything above works in the free version. PRO adds signals from outside the gym: sleep, stress, discomfort and its location, energy, HRV and diet phase. With them, the engine decides not only how much to increase the weight, but also when to push, when to hold back and when to protect you. Every additional data point enables a finer adjustment. You can try it free for 28 days.

## 9. How the app progresses

---

You don't need to calculate anything: TrueLift decide the load of your next session from your logs. Broadly speaking, this is how it works from your point of view:

- If you meet the target - every set at the planned reps and RIR - the app suggests a weight increase for the next session. The increment is small and proportionate to the exercise: larger for major compound lifts and smaller for isolation exercises.
- If you fall short, **maintains weight** so that you consolidate before going up again.
- The increase is not automatic or blind: it reflects how your previous session actually went. If you met the target but were at your limit, with very high effort or borderline performance, the increase will be smaller. If you clearly had capacity to spare, it may be larger. When the app chooses a cautious increase, the message explains this (for example, "Moderate increase...").
- **Anti-stagnation**: If you chain several sessions without completing the goal with the same weight, the app first warns you that the next attempt is decisive and, if you remain stuck, it suggests a small step back in the load to gain momentum and climb again by accumulating repetitions. This is what a good trainer would do: staying at the same weight for months is no longer an option.
- If you return after a **break of several weeks**, the app does not require you to continue where you left off: it suggests you pick up cautiously and "relearn" your real level in a few sessions, without marking weak sessions compared to your old self.
- Several days rated only "fair" while using PRO autoregulation? The engine does not freeze. It prompts you to review sleep and stress while continuing to progress cautiously with the information available.
- Your history remains stable: every session is evaluated using the criteria in place when it was saved. Changing diet phase later does not rewrite past sessions.
- Every suggested weight can be loaded with your equipment: barbell loads use the smallest available plate on both sides; machines progress plate by plate; and dumbbells follow the increment specified in Settings.
- Each session type progresses independently. If the same exercise appears on two different days, it advances separately in each session.

With double progression, you first accumulate repetitions within the range instead of increasing the weight every time. Once every set reaches the top of the range, the app recommends a weight increase and resets the repetition range.

## 10. Optional Features (PRO)

---

These features are optional: the app works without them. They are designed for those who want to fine-tune their training according to their condition and context. They are all part of the PRO version.

## Autoregulation (daily readiness)

This lets you record how you feel each day - sleep, stress, discomfort and energy. The app can then adjust the session to your actual readiness. If several poor days accumulate, it takes them into account and adapts training accordingly. When it detects meaningful fatigue, it may suggest a deload; if accepted, training enters deload mode for one or two weeks. Pain is also recorded by area (lower body, upper body or general), so knee pain can slow squat progression without affecting bench press. If you skip the daily check-in, the app does not assume you are fine - missing data is not a positive signal - and reminds you before suggesting increases.

How to rate sleep and mood. Always score according to your normality, not according to an ideal. If you slept the way you normally sleep—even though you have the feeling that “it's never perfect”—that's a 4, not a 3: 3 is for nights that are really worse than normal and 5 is for exceptional rest. The same goes for your mood and energy: an average day, with nothing that stands out for the worse, is a 4. Recording your normal day as a 4 is not settling (it's a good idea to keep trying to sleep and recover better), but it prevents the engine from reading a dip that doesn't really exist and slowing you down for no reason.

Muscle soreness is not joint pain. Distinguish between them when recording discomfort. Muscle soreness is a diffuse feeling in the muscle one or two days after training, especially after new exercises or higher volume. It is normal, forms part of the process and should not be recorded as pain. Joint pain is different: it is sharp or localised in a joint such as the knee, shoulder, elbow or hip, often appears during movement and signals that something may be wrong. Record genuine joint pain and always select the affected area - lower body, upper body or both - so the app protects only exercises involving that area. If ordinary muscle soreness is recorded as pain, the engine will hold you back unnecessarily; if genuine joint pain is ignored, it cannot protect you.

### HRV (heart rate variability)

Within autoregulation, you can enter your average overnight HRV each day, using the value from your watch or fitness tracker. It becomes another signal of daily readiness and recovery from training. You can optionally set a manual reference range supplied by your device if you already have a tracking history. Over time, the app learns your personal range from your own readings. The engine does not look only at the previous night; it also monitors the trend across recent days, which often reveals fatigue more reliably than one isolated reading. This is an advanced feature: if you do not measure HRV, leave it disabled.

## Readiness to train

When autoregulation is enabled, the app summarises your readiness with a Readiness to train score from 0 to 100, shown inside a coloured circle. Tap it to see which signals - sleep, stress, HRV, recent performance, accumulated training load and cardio load - are adding to or reducing the score.

## Diet phase

Indicate what nutritional phase you are in so that the app modulates the aggressiveness of the progression:

- **Deficit:** you are eating below maintenance calories (cutting). The app is more conservative with weight increases.
- **Maintenance:** maintenance. Balanced behavior (it is the default value).

- Surplus: you are eating above maintenance calories (bulking). The app is slightly more permissive with weight increases.

The effect becomes stronger the longer you remain in the selected phase. If you do not track your nutrition, leave it at Maintenance: this neutral option avoids incorrect interpretations. The free version is fixed at Maintenance.

## 11. Deload mode (deload)

---

A deload is an easier week designed to improve recovery: fewer sets, a higher RIR, roughly 10% less weight and progression temporarily paused. It does not erase progress; it protects it.

- You can activate it yourself in Settings (Deload mode). After one week, the app notifies you and lets you end the deload or continue it for one more week. If continued, it switches off automatically at the end of the second week.
- When the deload ends, progression resumes from the weights you used before it began, not from the reduced weights used during the easier week.
- With autoregulation enabled (PRO), the app may also suggest a deload when it detects accumulated fatigue, a drop in performance, several consecutive days of poor readiness even before your numbers decline, or an unusually demanding week of cardio. At appropriate intervals, it also asks you to consider honestly whether your body needs a deload - but only if you have trained consistently enough to require one.
- During a deload, the app confirms when you save each session that it is not evaluating performance or using that week for comparisons. This is intentional: the easier week does not distort your statistics or progression.
- Automatic suggestions are **sensible**: after finishing a deload there is a grace period without new suggestions (the small drop on return is normal and expected), and pain only counts as a reason if it is recent, not due to an episode that has already been resolved.

## 12. Volume Tab

---

This tab shows whether each muscle group is receiving an appropriate training volume. It displays two measures:

- Effective sets per week for each muscle group. The primary muscle counts x1 and secondary muscles count x0.5, based on your current exercises and set selection.
- Weekly frequency: how many days per week each muscle group is trained.

The colour guide provides a quick reference. The example below is for men; values for women are slightly different because women generally tolerate more volume.

| Sets / week | Meaning                            |
|-------------|------------------------------------|
| 4 or less   | too low                            |
| 5 – 9       | Minimum effective/maintenance      |
| 10 – 20     | Target zone (starts at the bottom) |
| 21 or more  | Very high No monitor recovery      |

In frequency, train a group **two or more days** per week is usually preferable for most goals.

## 13. Progress Tab

---

Here you see how you evolve over time. Includes, among others:

- **Last session tonnage:** the total kilos moved (weight × repetitions).
- **estimated 1RM:** An estimate of your one-rep max from your last set, calculated with a standard formula that takes into account RIR and protected against sets of very high reps, which are the ones that make the most noise.
- **estimated e1RM per session:** the evolution of your best estimated 1RM in each session, to see the trend. Essential to know if you are really progressing.
- **Recent availability (PRO):** A summary of your last few status days (green, amber and red).
- **Personal brands:** your best estimated 1RM per exercise. Only the **main multi-joint exercises** (squats, deadlifts, presses, chin-ups/pull-downs and rows), which are what mark your real strength.
- **HRV per day (PRO):** the evolution of your HRV measurements.
- **Performance:** A graph that indicates whether you are performing above or below your baseline, showing thresholds.
- **Duration of your sessions:** If you record in real time, the app notes by itself how long your workouts last and you will be able to see their evolution.

From this tab you can also generate the **Monthly report**- An HTML summary of your trained days, compliance, sessions, tonnage, repetitions and e1RM evolution, ready to share or save.

## 14. Support tools

---

### Plate calculator

Open it from the dumbbell icon at the top. Enter the target weight and bar weight, and the app tells you exactly which plates to load on each side, using only the plates configured as available, including fractional-plate limits. If the target cannot be assembled exactly, it shows the difference.

### Warm-up sets

On the same screen, enter the 1RM for a main exercise and the app suggests a five-set warm-up ramp, with three essential and two optional sets. Weight increases progressively while repetitions decrease, preparing you for your working sets without creating unnecessary fatigue.

### Rest timer

As described in the logging section, the rest timer manages recovery between sets and sounds an alarm when the time ends. You can enable or disable it in Settings (Countdown between sets).

Note: the app keeps the screen on. If you turn the screen off manually, the timer continues, but the alert will not sound until you turn the screen back on.

## 15. Share your training

---

TrueLift makes it easy to share your progress:

- **Share session:** from the history, generates an image card with the date, tonnage, total repetitions and details of the exercises, with the brand TrueLift and the web.
- **Monthly report-** From Progress, create a summary of the month to share or archive.

## 16. Backup

---

Your data lives on your mobile. To avoid losing them, use backups (in settings):

- **Export copy**- Save all your information (routine, history and settings) in one file. Keep it in a safe place.
- **Restore**: dump a copy on another mobile or after reinstalling. It replaces all current data with that of the copy, so use it with care.

## 17. Recommendations according to your level

---

### If you start

- Use **simple linear**: more efficient to start with.
- Prioritize the **technique** and write down the RIR honestly; It's what makes progression work.
- Set up your equipment, record your sessions and let the app guide you.

### If you have experience

- When linear progression stagnates, switch to **Double progression**.
- It will allow you to progress more slowly and precisely when simple progression is exhausted and increasing weights every week is not viable.
- Activate the **self-regulation (PRO)** and records your daily status, session effort and cardio: the more the motor "sees", the more finely it adjusts each decision.
- If you combine strength and endurance, record **all your cardio** with realistic duration and effort: the motor will monitor your total load, not just that of the weights.

## 18. Frequently asked questions

---

Will I lose my data when the PRO trial ends? No. Your routine and history remain saved; only advanced features are locked until you purchase PRO.

Is PRO a subscription? It can be, but does not have to be. Choose a recurring subscription, an annual payment or a one-time lifetime purchase. All options are managed through Google Play and can be restored on any phone using your Google account.

Why can I not change sets or RIR? Adjusting sets, RIR, repetitions and rest is a PRO feature. Try it during the free 28-day trial or unlock it with a purchase.

The suggested weight cannot be loaded with my plates. Check your equipment settings: 1.25 kg plates, the fractional-plate weight and quantity, and the dumbbell increment. The app only suggests weights that can be loaded with the equipment you specify.

**Do I have to use HRV and self-regulation?** No. They are optional. Progression works without them, but it will not have the optimizations provided in the PRO version.

**I don't control my diet, what do I put in the phase?** leave it in **Maintenance**. It is the neutral option.

I have missed the target at the same weight for several sessions. What happens next? The app detects this. It first warns you that the next attempt is decisive; if you remain stuck, it suggests a small reduction in load to break the plateau and build momentum again. You will not remain stuck

indefinitely.

**I've been without training for a few weeks, should I pick up where I left off?** The app will suggest that you resume with caution instead of demanding your last weight, and in a few sessions it recalibrates your real level. It is normal that the first sessions do not appear compared to your history: the engine is "collecting" again.

Why is this increase smaller than previous ones? The engine adjusts every increase to your actual previous session. It progresses cautiously after very demanding sessions, when RPE is high or performance is borderline, during a calorie deficit, or when RIR was not recorded. This is not an error; it shows the engine is doing its job.

What is session effort (RPE) used for when saving? It is an overall rating from 1 to 10. If recorded, the app uses it to refine the next increase and monitor accumulated fatigue. If you do not select a value, it simply does not count; the app never invents one for you.

My knee hurts. Will all progression stop? No. With autoregulation (PRO), selecting the pain area in your daily check-in only slows progression for affected exercises. Knee discomfort does not stop your bench press.

Does cardio affect my weights? It does not directly change strength loads, but it counts toward total training load. A week with much more cardio than usual contributes to fatigue signals and, with autoregulation (PRO), may prompt the app to suggest a deload.

## 19. About the author

---

TrueLift was created by Ruben Soro. His approach is evidence-based training without shortcuts or empty promises, helping you make sound progress in every session.
